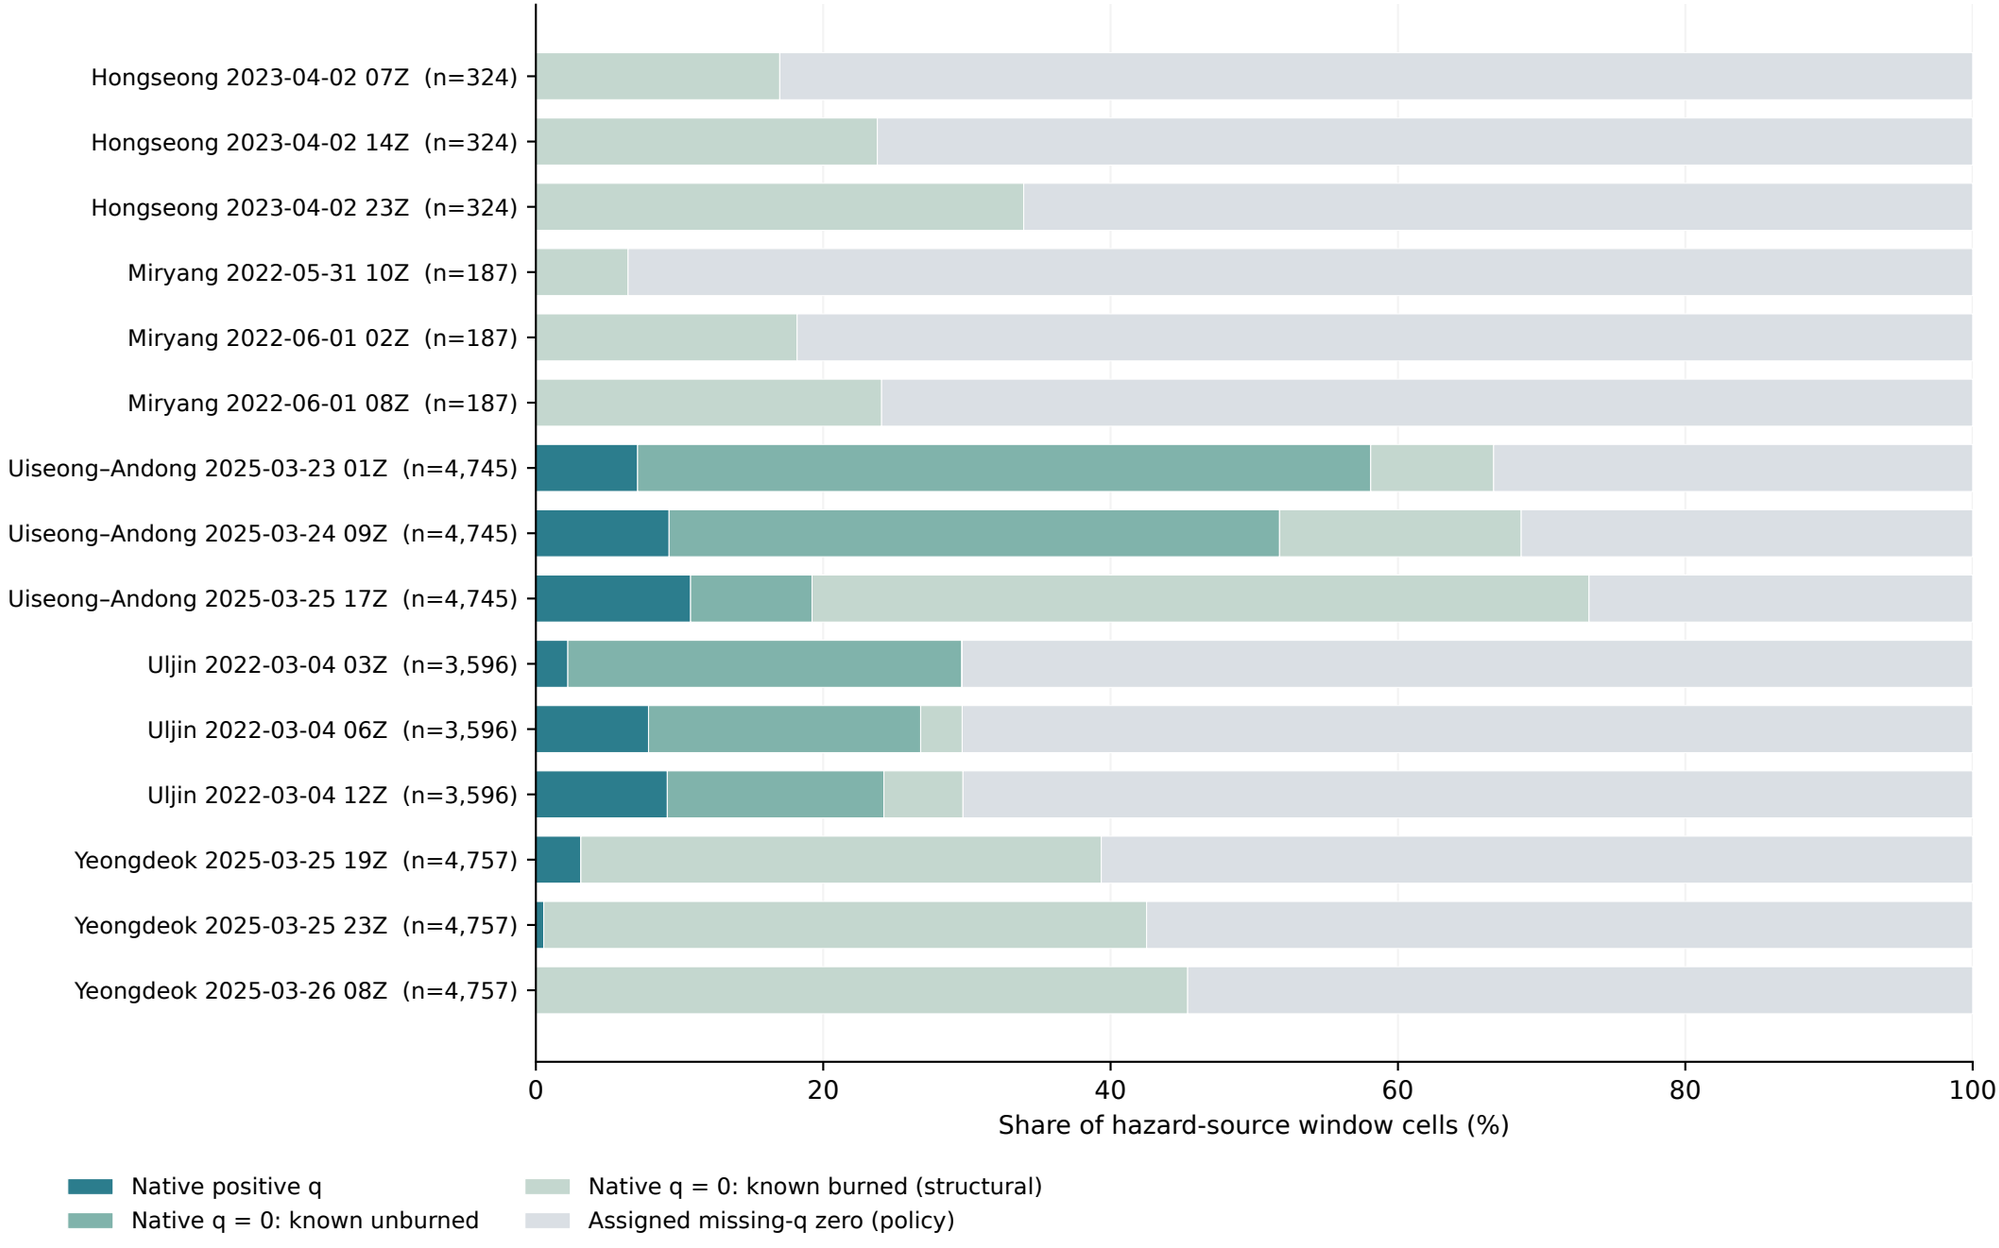
# Native probability and assigned zero have different meanings

Fifteen hazard-source windows • percentages of each window’s H × W cells • not route-occupancy or forecast-accuracy coverage



Native-valid q includes both zero categories: 6.4–73.3% per window; assigned missing-q zeros: 26.7–93.6%. Assigned zero is not estimated q.
Seven windows have no positive native q; eight have no sampled new ignition in any of four members. Four parent fires underlie five groups (UA and YD share KFS_01).
Unknown cumulative-state counts overlap these categories and are a separate source limitation. A null window means the whole event hazard-source grid, not necessarily the road graph domain.
