What this measurement cannot do

1. One camera cannot see depth. Speeds and flux are projections onto the picture; m/s holds only at the stated distance.
2. Embers are not air. They follow gusts 0.25 to 0.8 s late and fall at 2.5 to 8 m/s, so the arrows estimate the wind.
3. Calibration is uncertain. Road markings only scale the road surface, so airborne embers use an assumed distance range.
4. Only glowing, visible embers are counted, so counts are lower bounds. Flux is per length of a line in the picture, not NIST's per square metre.
5. Validated on synthetic video, a known-speed LED and plausibility checks; not side by side with a NIST Emberometer in a real fire.
